Experimental plots of different management regimes at Cerknica Polje

Project partners

Co-financer

The way the land is managed has a strong influence on the state of biodiversity and ecosystems in the area. The influence that land use has on habitats can be monitored in smaller model areas, and the knowledge gained then used for nature-friendly management on a larger scale.

For this purpose, we have created test plots in different areas of the intermittent Cerknica lake, where we test and study the response of vegetation to different mowing regimes. The test mowing regimes are mowing and harvesting once in 3 years, mowing and harvesting once in 2 years, mowing and harvesting once a year, mowing once a year without harvesting and a test plot without maintenance.

The test plots along the Drvošec trail near Pretržje are equipped with a permanent information board and are suitable for passive and active education of guided groups as well as for random visitors of the protected area. Have you already visited the test plots?
